

Chapter 4

Demography

Demography deals with the growth, distribution, density, characteristics, vital statistics, migration, etc., of human population. The present chapter is concerned with this subject as it applies to the population of Canada by bringing together recent data on these various demographic components.

The subject is treated by first providing a brief picture of population growth in Canada, followed by a summary from the 1971 Census of the geographical distributions of population and some of the principal demographic characteristics relating to population, households and families (Sections 4.1 to 4.4). Other statistics from the 1971 Census of Canada may be found in chapters 8, 11, and 14 of this edition on the subjects of labour force, agriculture, and housing, respectively.

A major portion of the chapter on Demography is concerned with the vital processes (fertility, mortality, nuptiality) which play such a major role in shaping population trends and composition (Sections 4.5 to 4.8).

The final section of the Demography chapter deals briefly with the important migration factors (immigration, emigration and internal migration) which also exert a significant influence on population change and structure (Section 4.9).

4.1 Population growth

The most fundamental fact about a population is its rate of growth which affects almost every aspect of the national life. The opening up of a new continent and the gradual evolution of an industrial and urban economy form the historical background for population growth in Canada. Several demographic elements have combined to produce this growth: births, deaths, immigration and emigration, which are the processes, or components, of population change.

4.1.1 The early period

The growth of Canada's population today is the culmination of a trend which began around the early 17th century with the arrival of the first French settlers. From this beginning, the population of the area now known as Canada (excluding Newfoundland) grew from a handful of colonists and an unknown number of native Indians and Eskimos in 1611 to about 2.4 million in 1851 and 3.7 million at the first Census of Canada in 1871. Rough estimates indicate there were about 136,000 Indians in 1851.

Growth rates in the early settlement years were very irregular: the immigrant population grew rapidly while the native population remained almost stationary or declined as a result of attrition from warfare and disease. Between 1681, when the number of settlers passed the 10,000 mark, and 1851 the average annual growth rate of the non-native population in each decade varied between 1.6% and 4.5%; the average annual growth rate for the whole period was 3.2%. The small size of the initial population and the continuous expansion into empty lands were contributing factors in the rapid growth rates in the early periods.

The decade 1851-61 was one of surging growth, second only to the growth rate in the first decade of the present century (Table 4.1). The average annual growth rate during this period was 2.9%, with about 23% of the total population increase due to net migration; over 350,000 immigrants arrived and there was very little emigration. A long period of slow growth followed and lasted until the beginning of the 20th century. Between 1861 and 1901 the average growth rate was closer to 1%, matched only by the rate during the depression period of the 1930s. This slow growth toward the end of the last century was due to heavy emigration resulting in a net migration loss (Table 4.2). Emigrants included elements of both the Canadian and foreign-born populations. While many immigrants continued to come to Canada during this period a large number of them re-emigrated to the United States where prospective settlers were offered more favourable economic and climatic conditions. The westward movement in the United States attracted not only settlers from every part of that country, but from Canada as well.
